Research Or Analytical Question:

Do ride-share and public transportation users differ in communication apprehension?

Answer, Response, + Summary of Results

Yes.

First, there was a consistent trend where people who use ride share or public transportation (or both) had significantly lower communication apprehension than those who use neither, and that trend continues as frequency of use increases.

Ride-share-only users had lower communication apprehension on average than public-transportation-only users and those who use both modes (see Table 1).

Table 1	Transportation	Avg. Communication Apprehension/Question
	Neither	2.11
	Public Transportation Only	1.59
	Ride Share Only	1.17
	Public Transport & Ride Share	1.23

When looking at frequency of use, ride-share frequency was a significant negative predictor of communication apprehension whereas public transportation frequency was not. Figure 1 helps visualize this pattern: the black line shows the overall negative relationship between transportation-use frequency and communication apprehension, while the other lines show the trends among ride-share-only and public-transportation-only users. The ride-share group shows a more pronounced decrease in communication apprehension as frequency increases, while the trend among public-transportation-only users is weaker.

Remaining Questions

Figure 1

While it was found that ride-share frequency was a significant negative predictor of communication apprehension ($b = -0.23$, $p < .001$), whereas public-transport frequency was not ($b = -0.05$, $p = .318$), the difference between these two relationships has not yet been directly tested for statistical significance.
