Research Question: Does age predict communication apprehension?

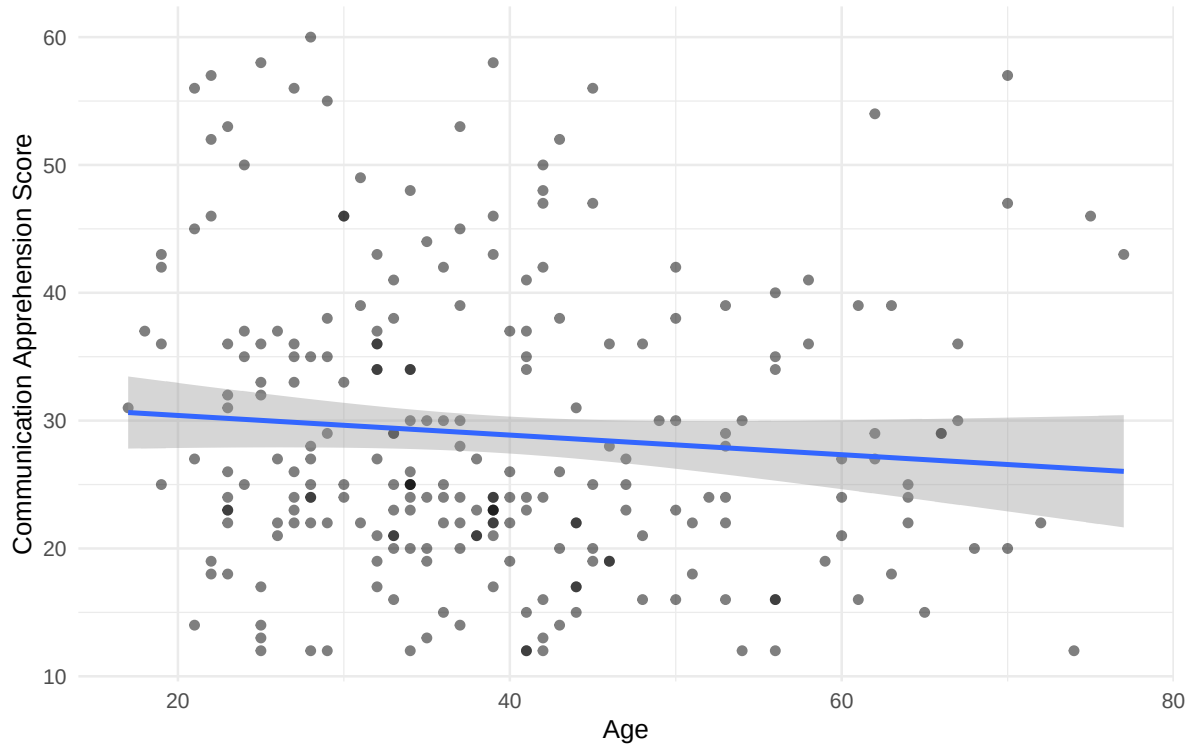

Figure 1: Relationship between age and communication apprehension.

Answer, Response, + Summary of Results

This analysis examined whether age predicts communication apprehension among 241 participants using combined group discussion and interpersonal PRCA scores. The scatterplot showed a slight downward trend, but scores varied widely across ages. A Pearson correlation and linear regression found a weak negative relationship, $r = -0.089$, $b = -0.077$, $p = 0.168$. Age explained only 0.8% of the variation, so it was not a significant predictor of communication apprehension.

What Questions or Uncertainties Remain?

A Future analyses could examine whether factors such as transportation habits, employment, education, or other demographic and behavioral characteristics are associated with communication apprehension.
